

# Photons in Large Momentum Transfer Processes

J.F. Owens  
Physics Department, Florida State University

2006 CTEQ Summer School  
July 1 - July 9, 2006  
Rhodes, Greece

# Outline

1. Introduction
  - Why photons?
  - Some history
2. Theory overview and comparison to selected data
  - Direct Photon Production
  - Jet Photoproduction
3. Theoretical improvements
  - Resummation techniques
  - Some applications
4. Conclusions
5. Appendix: Notation, kinematics, and other useful information

## Why Photons?

- Well understood electromagnetic interaction
- Well defined probe of strong interaction dynamics
- Classic examples
  - Deep inelastic scattering
  - Lepton pair production
  - $e^+e^- \rightarrow$  hadrons
- Direct photons, photoproduction, and two photon processes continue this history
- Calculations for the proposed International Linear Collider will rely on a detailed understanding of the treatment of photons in high energy processes

## Direct Photons - Some Early History

Late 70's - Early 80's

- Fixed target experiments, ISR (pp), prior to  $\bar{p}p$  colliders
- Jet identification difficult - and controversial!
- Photons offered a way to directly probe the scattering subprocesses  
 $\Rightarrow$  study parton-parton scattering without jet ID problems

Theoretically Interesting

- QCD hard scattering formalism not yet fully confirmed
- Competition from the Constituent Interchange Model
- $\gamma/\pi$  ratio offered some interesting tests of QCD vs CIM - G. Farrar, Phys. Lett. **B67**, 337 (1977)
- QCD Compton process ( $qg \rightarrow \gamma q$ ) proposed as a *test* of QCD - H. Fritzsch and P. Minkowski, Phys. Lett. **B69**, 316 (1977)

Early reviews: T. Ferbel and W.R. Molzen, Rev. Mod. Phys. **56**, 181 (1984);  
J.F. Owens, Rev. Mod. Phys. **59**, 465 (1987)

## Time Passes ...

- Higher energies with development of  $\bar{p}p$  colliders
- Greater reach in transverse momentum
- Jet production, detection became routine
- QCD hard scattering expectations confirmed
  - Event structure with two jets, balancing in  $p_T$  observed
  - Di-jet angular distribution confirmed
  - QCD expectations for direct photons also confirmed - with some exceptions
- Focus shifted somewhat from *testing* QCD to *using* QCD to constrain parton distribution functions and to perform searches for new physics.

QCD Compton subprocess involves an initial state gluon

$\Rightarrow$  direct photon production is sensitive to the gluon distribution especially in processes where the QCD Compton subprocess dominates, *e.g.*,  $pp$  scattering

## Today

- Wide range of data available
  - Data review by W. Vogelsang and M.R. Whalley, J. Phys. **G23**, Suppl. 7A, A1-A69 (1997)
  - Online database at <http://durpdg.dur.ac.uk/HEPDATA>
- Usual direct photon talk emphasizes problems describing  $p_T$  distributions

perhaps suggesting that there is something wrong with direct photon theory!

But direct photon theory *is* QCD ...

The situation is really more complex ...

Key predictions of QCD concerning direct photon production include

- Event structure
  1. Where are the photons produced?
  2. How are they correlated with jets?
- Energy dependence of the cross section
- Absolute cross section

Key element underlying each of these is the set of parton-level subprocesses involved.

Can one measure the properties of the subprocesses?

Yes!

# Plan

- Review basic theoretical ingredients
- Compare theory and data using observables which directly test the underlying production mechanisms
  - $\gamma$ -jet mass distribution
  - $\gamma$ -jet angular distributions
  - Event structure - correlations with produced hadrons
- Compare/contrast with jet photoproduction - which uses the same subprocesses
- Finally - examine the predictions for the  $\gamma$   $p_T$ , rapidity, and center-of-mass energy dependence and compare to other examples of single particle inclusive production.

## Theory Overview

- Lowest Order:  $\mathcal{O}(\alpha\alpha_s)$ 
  1.  $qg \rightarrow \gamma g$  QCD Compton
  2.  $q\bar{q} \rightarrow \gamma g$  annihilation
- The single photon invariant cross section is given by a convolution with the beam and target parton distribution functions

$$d\sigma(AB \rightarrow \gamma + X) = G_{a/A}(x_a, \mu_F) dx_a G_{b/B}(x_b, \mu_F) dx_b \frac{1}{2\hat{s}} \sum_{ab} |M(ab \rightarrow \gamma c)|^2 d^2PS$$

- $d^2PS$  denotes two-body phase space and  $\mu_F$  is the factorization scale

- See the appendix for more details about variables and four-vectors
- Also see the Handbook of Perturbative QCD on the CTEQ web site <http://www.cteq.org>. The appendix has additional information on how to calculate cross sections for hadronic processes starting at the parton level.

Next-to-Leading Order:  $\mathcal{O}(\alpha\alpha_s^2)$

1. one-loop virtual contributions
  2.  $q\bar{q} \rightarrow \gamma gg$
  3.  $gq \rightarrow \gamma qg$
  4.  $qq' \rightarrow \gamma qq'$  plus related subprocesses
- In the next order one sees a new configuration wherein the photon is no longer isolated. Instead, it may be radiated off a high- $p_T$  quark produced in the hard scattering process.

- Consider the subprocess  $q(1)q(2) \rightarrow q(3)q(4)\gamma(5)$
- Examine the region where  $s_{35} = (p_3 - p_5)^2 \approx 0$

$$\overline{\sum} |M(qq \rightarrow qq\gamma)|^2 \approx \frac{\alpha}{2\pi} P_{\gamma q}(z) \frac{1}{s_{35}} \overline{\sum} |M(qq \rightarrow qq)|^2$$

- An internal quark line is going on-shell signalling long distance physics effects
- Gives rise to a collinear singularity
- Can factorize the singularity by introducing a *photon fragmentation function*

## Photon Fragmentation

- Photon is accompanied by jet fragments on the *same* side
- Factorize the singularity and include it in the bare photon fragmentation function
- Sum large logs with modified Altarelli-Parisi equations

$$Q^2 \frac{dD_{\gamma/q}(x, Q^2)}{dQ^2} = \frac{\alpha}{2\pi} P_{\gamma q} + \frac{\alpha_s}{2\pi} [D_{\gamma/q} \otimes P_{qq} + D_{\gamma/g} \otimes P_{gq}]$$
$$Q^2 \frac{dD_{\gamma/g}(x, Q^2)}{dQ^2} = \frac{\alpha_s}{2\pi} \left[ \sum_q D_{\gamma/q} \otimes P_{qg} + D_{\gamma/g} \otimes P_{gg} \right]$$

- As with hadron pdfs and fragmentation functions, can't perturbatively calculate the fragmentation functions, but the scale dependence is perturbatively calculable
- Note the  $P_{\gamma q}$  splitting function - represents the pointlike coupling of the photon to the quark in  $q \rightarrow \gamma q$

# Fragmentation Component

- The situation has become more complex
- Expect to see two classes of events
  1. Direct (or pointlike) - no hadrons accompanying the photon
  2. Fragmentation (or bremsstrahlung) - photon is a fragment of a high- $p_T$  jet. Part of the fragmentation function is perturbatively calculable.
- Expect (1) to dominate at high- $p_T$  since the energy is not shared with accompanying hadrons.
- The  $P_{\gamma q}$  splitting function gives rise to the leading high  $Q^2$  behavior going as  $\alpha \log(Q^2/\Lambda^2) \sim \frac{\alpha}{\alpha_s}$  (see the Appendix for a derivation)

So, to our list of contributions add those involving **photon fragmentation functions**

- $\mathcal{O}(\alpha\alpha_s) : \frac{d\sigma}{dt}(ab \rightarrow cd) \otimes D_{\gamma/c}$
- $\mathcal{O}(\alpha\alpha_s^2) : \frac{d\sigma}{dt}(ab \rightarrow cde) \otimes D_{\gamma/c}$

## Some Comments

- Photons can be produced as fragments of jets, as is also the case for particles
- Photon production therefore involves all of the subprocesses relevant for jet or particle production
- In addition, one also has the pointlike production processes

Photon production is *more* complicated than jet production, not *less*

# Next-to-leading-order Calculations

- Have to integrate over unobserved partons. There are regions of phase space where partons can become parallel to each other (collinear) or soft. Both regions are singular.
- Usually use dimensional regularization to regulate the divergences

Two types of programs exist

1. Phase space integrations done symbolically so expressions for the integrated parton-level subprocess cross sections exist. Integrations over the parton momentum fractions  $x_a, x_b$ , and  $z_c$  done numerically. This approach is suitable for the single photon inclusive cross section.
2. All integrations done via Monte Carlo
  - Phase space slicing method - see the Appendix
  - Subtraction method

With Monte Carlo programs one can examine correlations between the photon and other partons in the final state.

## Short summary of two-body kinematics

The following relations are useful when trying to understand the regions of the parton variables which are important for specific observables. More information is available in the appendix.

Consider a photon and a jet produced with approximately balancing  $p_T$  and (pseudo)rapidities  $\eta_\gamma$  and  $\eta_{jet}$  in the hadron-hadron center-of-mass system.

$\gamma$ -jet invariant mass  $M$ :  $M^2 = x_a x_b s$     $\gamma$ -jet rapidity  $Y$ :  $Y = (\eta_\gamma + \eta_{jet})/2$

Scattering angle in the  $\gamma$ -jet rest frame:  $\cos \theta^* = \tanh(\eta_\gamma - \eta_{jet})/2$

Parton momentum fractions

$$\begin{aligned} x_a &= x_T (e^{\eta_\gamma} + e^{\eta_{jet}})/2 = M e^Y / \sqrt{s} \\ x_b &= x_T (e^{-\eta_\gamma} + e^{-\eta_{jet}})/2 = M e^{-Y} / \sqrt{s} \end{aligned}$$

Note: for  $Y \approx 0$  one is sensitive to  $x_a \approx x_b \approx M/\sqrt{s}$ . For  $\eta_\gamma \approx \eta_{jet} \approx 0$  one has  $x_a \approx x_b \approx x_T$ , but this is only a guide, since the cross sections will involve some integrations.

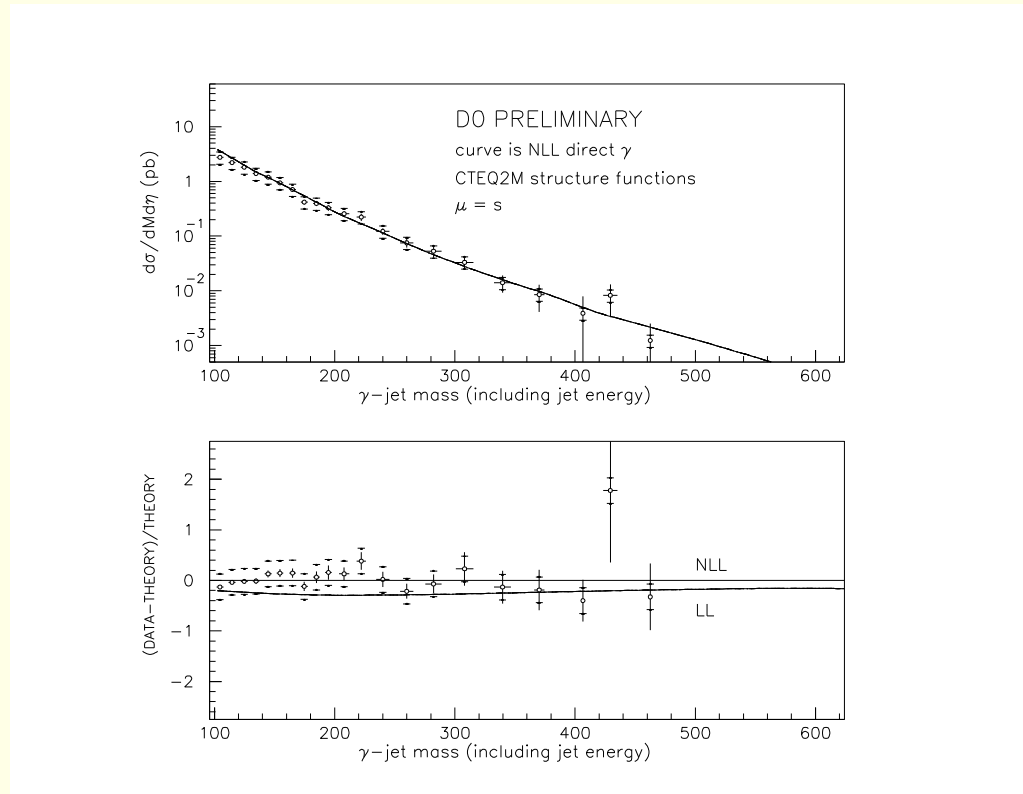

## Comparison to Data

- Want to first examine data which yield information on the underlying parton subprocesses
- Need  $\gamma$ -jet observables
  - $\gamma$ -jet invariant mass
  - $\gamma$ -jet angular distributions
- Start with Tevatron data
  - Higher energies enable jet identification and reconstruction as compared to fixed target data
  - Essentially the only direct photon data with identified jets

## $\gamma$ -jet invariant mass distribution

- Preliminary data from DØ Run I

- Comparison suggests that the photons are being produced at the expected level, but doesn't, by itself, have much to say about the subprocesses
- Note that the relevant region of  $x$  in the pdfs is  $x \approx M/\sqrt{s}$

## $\gamma$ -jet angular distributions

- QCD Compton and annihilation subprocess both behave as

$$\frac{d\sigma}{d\hat{t}} \sim (1 - \cos(\theta^*))^{-1} \text{ as } \cos(\theta^*) \rightarrow 1$$

- Other parton-parton scattering subprocesses  
( $qq \rightarrow qq, qg \rightarrow qg, gg \rightarrow gg$ , etc.) behave as

$$(1 - \cos(\theta^*))^{-2}$$

- This means that the  $\gamma$ -jet angular distribution should be flatter than that observed in jet-jet final states.
- See the appendix for a derivation of these relations

## Direct Measurement of the $\gamma$ -jet angular distribution

- Measuring both  $\eta_\gamma$  and  $\eta_{jet}$  allows one to reconstruct  
 $\cos \theta^* = \tanh(\eta_\gamma - \eta_{jet})/2$
- Both DØ and CDF have measured the  $\gamma$ -jet angular distribution

- Both experiments observe a shape consistent with expectations
- Direct photon production is dominated by subprocesses which yield a flatter angular distribution than is observed for dijet production

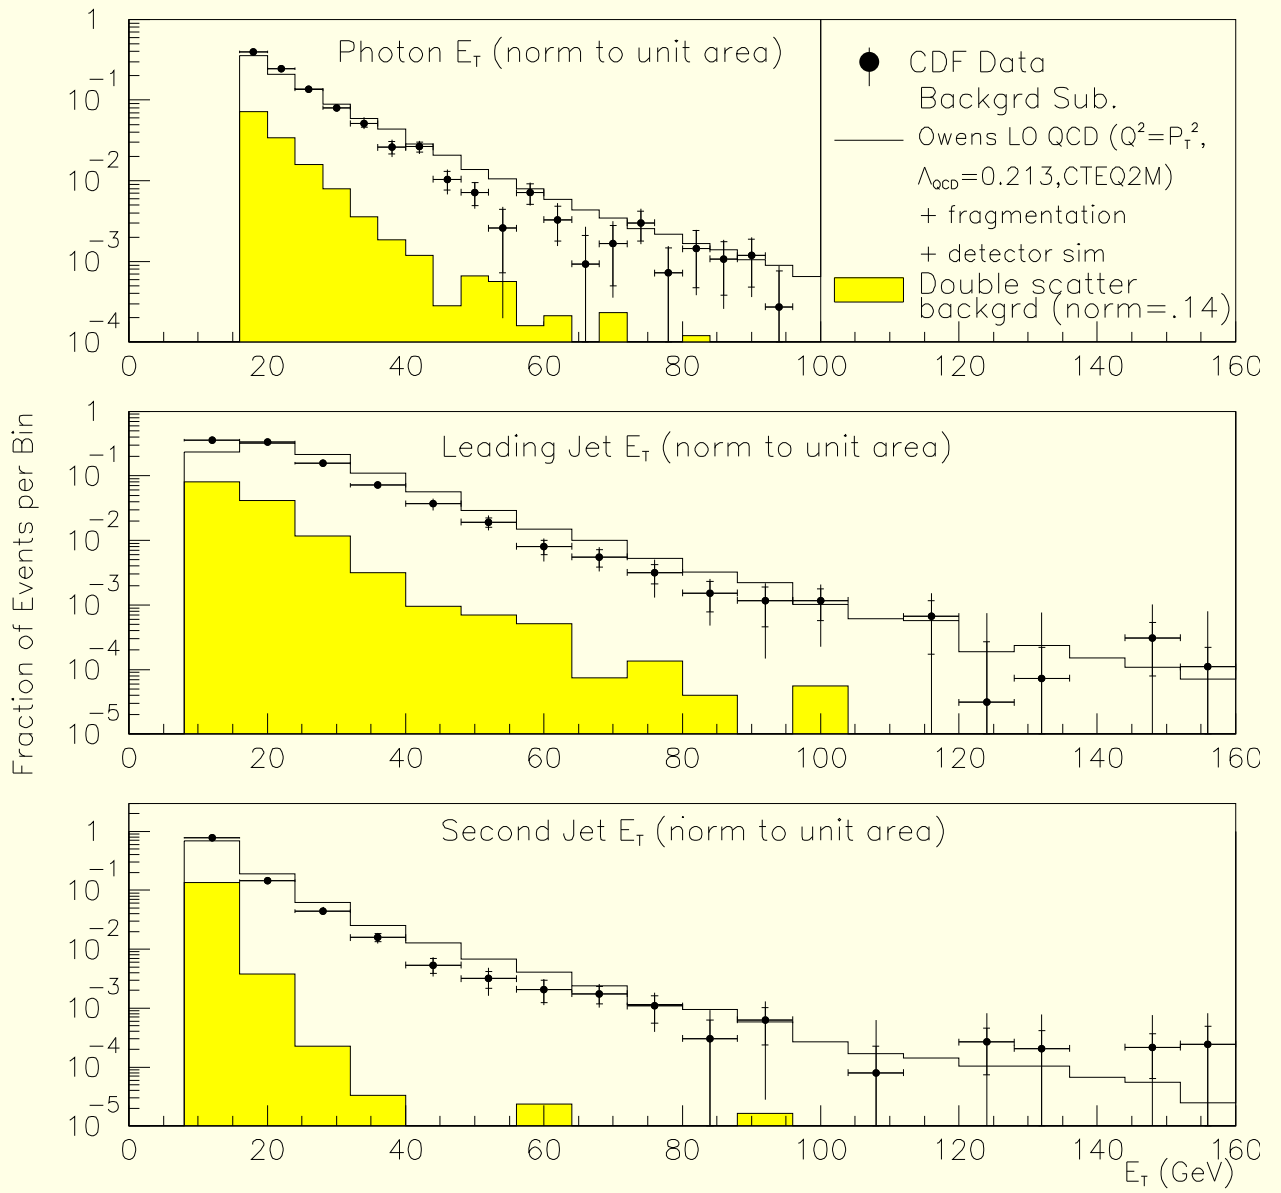

## Three-body Final States

- The next-to-leading-order calculations involve the addition of  $\gamma+2$  parton final states
- Should be able to examine correlations between the  $\gamma$  and the two final state jets in order to test the underlying subprocesses
- Such measurements have been done by CDF - Abe et al., Phys. Rev. **D57**, 67(1998)
- Caveat - these comparisons are to tree-level predictions based on  $2 \rightarrow 3$  subprocesses, so they are not full next-to-leading-order predictions.

# CDF Preliminary

# CDF Preliminary

## Event Structure

- Lowest order Compton and annihilation subprocesses correspond to an isolated photon recoiling against a jet
- Fragmentation contributions add a component where the photon is accompanied by the hadronic fragments of the parent jet
- Expect to see fewer hadrons on the photon side of the event than would be the case with a hadronic trigger
- Results from UA-2 (R. Ansari et al., Z. Phys. **C41**, 395(1988)) show the reduced number of same side hadrons for photon triggers
- Note that the amount of hadronic activity for photon triggers is larger than that for  $W$  production, while being smaller than that for hadronic triggers
- Consistent with a superposition of direct and fragmentation components

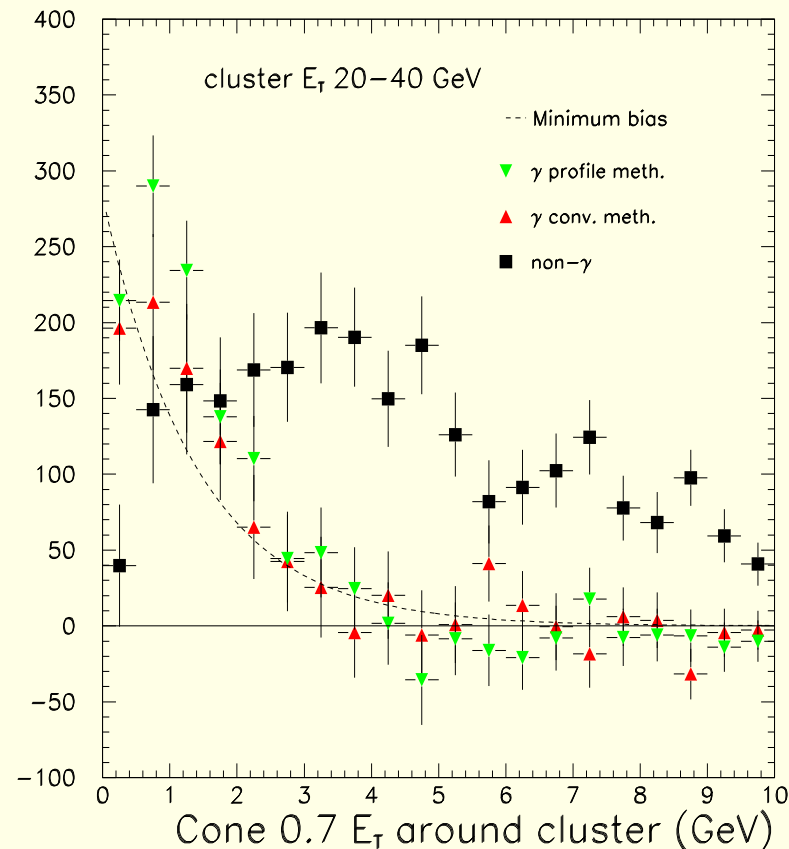

Figure 12

Similar result seen in preliminary CDF data

$E_T$  inside a cone of radius 0.7 about the photon looks just like minimum bias case - and not at all like that for hadronic events

Difficult to identify fragmentation component due to background from beam fragments

## Recap

- Thus far we have seen that
  - Photons are produced with the expected  $\gamma$ -jet angular distribution which is flatter than that for dijets
  - Photon-jet rapidity correlations are as expected
  - Photon+2jet events appear to behave as expected
  - Photons appear to be accompanied by fewer hadrons than for purely hadronic triggers, although more than for  $W$  events
- All of these items suggest that the basic mechanism for producing high- $p_T$  photons is as expected from QCD
- Is there any other way to probe the dynamics of photon-parton interactions that tests these same mechanisms?

Yes! Jet Photoproduction

## Jet Photoproduction

- The same subprocesses are involved, but with the photon crossed to the initial state

$$qg \rightarrow \gamma q \quad \Rightarrow \quad \gamma q \rightarrow qg \text{ etc.}$$

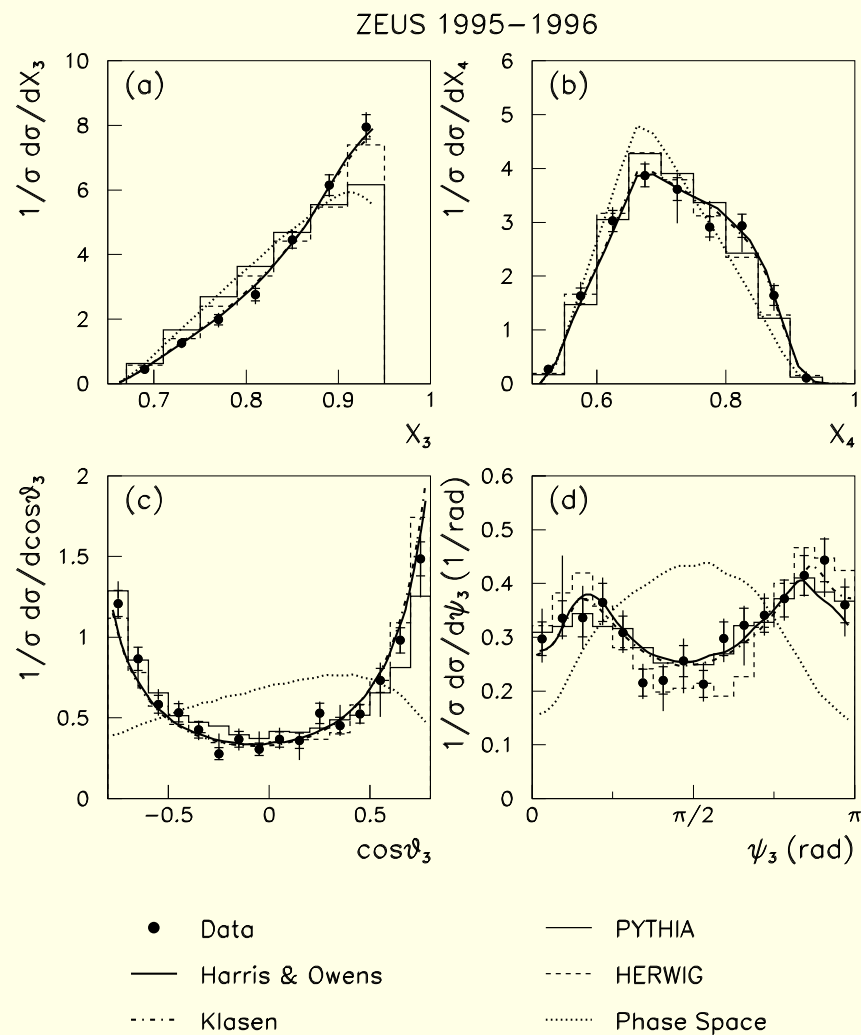

- Role of photon fragmentation is now in the initial state where it is treated using a photon pdf
- Details may be found in my CTEQ 2001 summer school lecture at [www.cteq.org](http://www.cteq.org)

## Examples

- Consider several different processes in order of increasing complexity concerning the interactions of the photons
- Photoproduction of three-jet final states
  - Calculation based on  $\mathcal{O}(\alpha\alpha_s^2)$  subprocesses
    1.  $\gamma q \rightarrow qgg$
    2.  $\gamma g \rightarrow q\bar{q}g$
    3.  $\gamma q \rightarrow qq'\bar{q}'$
  - Consider three identified high- $p_T$  jets with high three-jet mass
  - Only looking at the pointlike interaction of the photon - no resolved contribution
  - Calculation at this level is lowest order (LO) and also leading-log (LL)
  - Compare to data from the ZEUS Collaboration ( hep-ex/9810046)
    - \* three-jet mass  $M_{3j}$
    - \* energy fractions: jets ordered in energy with  $E_3 > E_4 > E_5$  and energy fractions defined as  $x_i = 2E_i/M_{3j}$
    - \* jet angular distributions

- Energy fractions are ordered with  $E_3 > E_4 > E_5$
- $\cos \theta_3, \phi_3$  describe the jet orientations

Observe good agreement between matrix element calculations and the data and also between shower Monte Carlo calculations and the data

## Single jet and Dijet Photoproduction

- As noted earlier, there will be two components
  - direct or pointlike - photon contributes directly to the hard scattering
  - resolved - both photon and proton parton distributions convoluted with parton-parton scattering subprocesses
  - at  $\mathcal{O}(\alpha\alpha_s^2)$  and beyond, specific diagrams can contribute to both. Need an experimental definition to distinguish between the two classes. For example the ZEUS Collaboration has used the following for dijet final states:

$$x_\gamma^{obs} = (E_T^{jet1} e^{-\eta_{jet1}} + E_T^{jet2} e^{-\eta_{jet2}}) / 2E_\gamma$$

- positive  $\eta$  corresponds to the direction of the proton
- consider two samples with  $x_\gamma^{obs} > .75$  (mostly direct) and  $x_\gamma^{obs} < .75$  (mostly resolved)

## Dijet angular distribution

- $\gamma q \rightarrow qg$  and  $\gamma g \rightarrow q\bar{q}$  are fermion exchange processes which have an angular distribution going as  $1/(1 - \cos \theta)$  in the dijet center of mass system
- typical boson exchange processes in the resolved part  $qq \rightarrow qq, qg \rightarrow qg, gg \rightarrow gg$  etc., behave as  $1/(1 - \cos \theta)^2$  which is much steeper

Compare to data from the ZEUS Collaboration (M. Derrick *et al.*, Phys./ Lett. **B384**, 401 (1996).)

Curves from Harris and Owens, Phys. Rev. D**56**, 4007 (1997). Dashed lines are LO and solid are NLO.

Note the different scales on these normalized distributions - the dominantly resolved sample has a much steeper distribution

## Aside

Why is it possible to separate the direct and resolved components in jet photoproduction, yet it is difficult to isolate the fragmentation or bremsstrahlung component in direct photon production?

- In jet photoproduction one has a sample with two identified jets in the final state. These can be used to reconstruct  $x_\gamma$  and  $x_p$  directly.
- Higher order effects and smearing due to beam fragments entering the jet cones smear out the direct component peak at  $x_\gamma = 1$ , but one can still define two samples of events which are dominantly resolved or dominantly direct.
- In contrast, for direct photon production
  - Some of the fragmentation contribution is removed by isolation cuts used in the trigger (see later)
  - For fragmentation events, one must reconstruct  $x_a, x_b$ , and the fragmentation variable  $z_c$ . There is not enough information.
- Accompanying hadronic energy difficult to distinguish from beam fragments
- This means that one can not use the accompanying hadronic energy as a flag for fragmentation events.

## Lessons Learned

- Photoproduction data support the view that photons interact with partons as expected in QCD
- Two-component picture of the dynamics
  - Direct (point-like) and resolved components in jet photoproduction - resolved piece uses a photon parton distribution to resum large logs coming from configurations where partons are produced collinear with the incoming photon
  - Direct (point-like) and fragmentation components in direct photon production - fragmentation piece uses a photon fragmentation function to resum large logs coming from configurations where the photon is a fragment of a jet and there are partons which are produced collinear with the outgoing photon.
- So, to this point it seems that the theory of direct photon production is supported by the data.

**Then, what is all the fuss about?**

## Single Photon Inclusive Cross Section

- Integrate over all partons, leaving only the photon as being observed
- In some sense this is the hardest measurement to interpret since if there is a disagreement between theory and experiment one has few clues as to the origin - all other details have been integrated out
- On the other hand, the inclusive nature of the observable makes the calculation easier - you don't have to model the distributions that are integrated over. Rather, you only have to get the integral over the distribution correct.
- Can measure - and calculate - the photon  $p_T$  and  $\eta$  distributions
- $p_T$  spectrum is steeply falling so that it is especially susceptible to resolution smearing effects on the experimental side and approximations made in the theoretical calculations

Calculations use the same techniques as described previously

- Analytic calculations result in faster running programs, since many of the integrations have already been done and only the convolutions with pdfs and fragmentation functions need to be done.
- Monte Carlo based programs are able to investigate the effects of the photon isolation cuts to be discussed below, although approximation techniques exist so that the analytic programs can also invoke these cuts.

## Tevatron data

CDF:  $\sqrt{s} = 1800, 630$  GeV,  $|\eta| < 0.9$

DØ:  $\sqrt{s} = 1800, 630$  GeV,  $|\eta| < 0.9, 1.6 < |\eta| < 2.5$

- Agreement looks good when plotted on a logarithmic scale
- Confirms expectation that the QCD description of direct photon production is correct
- But what if we look closer ...?

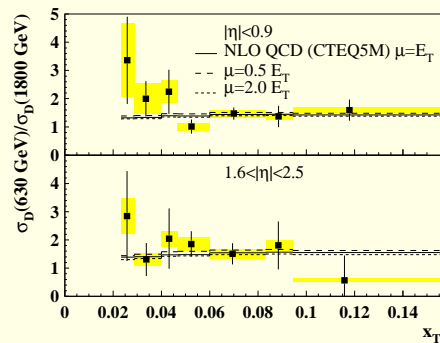

Look on a linear scale ...

Both CDF and DØ see an excess at the low  $p_T$  end in the central region

- Problem seen by CDF at both 1800 and 630 GeV
- Excess occurs at low  $p_T$ , not at fixed  $x_T$ , so the solution can not be a simple adjustment of the pdfs
- Effect also seen by UA-2

- at low  $p_T$  also seen by DØ at 630 GeV

## Isolation Cuts

- So, what can explain the disparity between shapes of the experimental and theoretical distributions?
- One item to consider is that these are not truly inclusive measurements. Rather, they are measurements of inclusive cross sections for *isolated* photons.
- Algorithms are different for each experiment (UA-2, CDF, DØ) but all limit the allowed hadronic energy in the vicinity of the electromagnetic trigger  
⇒ fragmentation component is reduced
- Expect fragmentation to be most important at the low  $p_T$  end of the distribution
- Fragmentation provides only a portion of the available energy to the photon. The pointlike or direct subprocesses are more efficient and so dominate at high values of  $p_T$
- Errors on modeling the effects of the isolation cuts could especially affect the low  $p_T$  end of the spectrum

## Specific Example - CDF cone algorithm

- Require that there be less than 1 GeV of hadronic transverse energy in a cone of radius

$$\mathcal{R} = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2} < 0.4$$

about the direction of the photon.

## Theoretical modeling (phase space slicing method)

- Must treat the two- and three-body contributions separately
- For the  $2 \rightarrow 3$  pointlike subprocesses, one can explicitly enforce the isolation condition on an event-by-event basis in the Monte Carlo at the parton level.

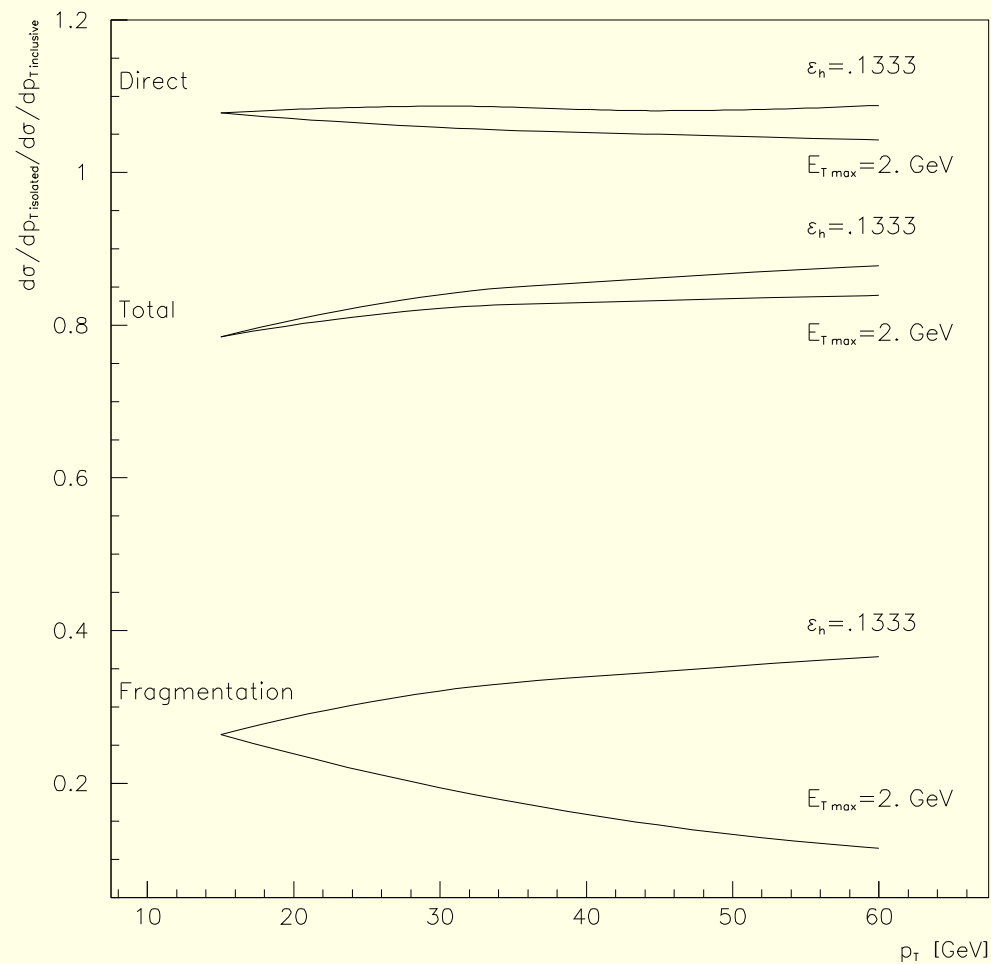

- For the two-body fragmentation component there is no dependence on  $\mathcal{R}$  since the fragmentation functions are inclusive quantities.
  - Work in the collinear approximation (all emitted partons or photons are collinear with the parent parton)
  - parent parton transverse momentum is  $p_{Tpart}$
  - photon transverse momentum is  $p_{T\gamma} = zp_{Tpart}$
  - hadronic  $E_T$  is  $(1 - z)p_{Tpart} = (1 - z)p_{t\gamma}/z$ .
- Requiring that the hadronic  $E_T$  is less than  $E_{Tcut}$  results in

$$z > \frac{1}{1 + E_{Tcut}/p_{T\gamma}}.$$

- One can also enforce a similar isolation condition on the  $2 \rightarrow 3$  fragmentation component

## Example

Study of the behavior of the isolated photon cross section by Catani, Fontannaz, Guillet, and Pilon, hep-ph/0204023

Ratio of isolated to inclusive for the total and each component

Consider the “Total” curve for  $E_{Tmax} = 2$  GeV. The cone radius is  $\mathcal{R} = .7$  (similar to  $E_{Tmax} = 1$  GeV in a cone of radius .4)

- $\sim 22\%$  reduction due to isolation at  $p_T=15$  GeV
- Expected effect of the isolation slowly decreases as  $p_T$  increases
- Even if the isolation was *totally removed*, the cross section would only increase by 28 %.

Strongly suggests that the modelling of the isolation cuts is not responsible for the discrepancy between theory and experiment

## Fixed Target and Lower Energy Collider Data

It is now time to consider the situation for the inclusive cross section at lower energies

## Comments

1. Data/Theory plotted versus  $x_T$
2. Data plotted at same  $x_T$  but different  $\sqrt{s}$  correspond to different  $p_T$ 's
3. E706 higher than theory, UA6 somewhat above theory, WA70 and theory agree
  - Likely that there is some experimental inconsistency here since the range in  $\sqrt{s}$  is relatively small and it would take a significant modification of the theory to explain all three sets simultaneously.
4. See some shape disagreements among the ISR experiments
5. Plotted on this scale, the previously noted deviations of the theory from the CDF and DØ data look pretty darned small!

- Similar plot showing new PHENIX data (nucl-ex/0504013)

- Agreement is comparable to that for other collider experiments and better than for the fixed target regime

## Example - UA-6

- Measured both  $pp$  and  $\bar{p}p$  at  $\sqrt{s} = 24.3\text{GeV}/c$
- Initial state gluon and gluon fragmentation contributions cancel in the  $\bar{p}p - pp$  difference

- Theory below the data at the lower end of the  $p_T$  range
- Rapidity theory curves are flatter than the data

- Cross section difference cancels contributions from gluons
- $p_T$  difference is well described
- Rapidity theory curve is somewhat flatter than the data
- So, the situation is mixed - the  $\bar{p}p$  and  $pp$  curves are individually below the data, the  $p_T$  difference is well described, while the rapidity difference curve is a bit too flat

So what is going on?

- Theory and data have different shapes for  $\sqrt{s} = 630, 1800$  GeV with the theory being flatter than the data
- Some of the lower energy experiments show this same behavior to an even larger degree - others do not
- Critical review of the situation for the lower energy experiments: Aurenche, Fontannaz, Guillet, Kniehl, Pilon, and Werlen, hep-ph/9811382

Is this behavior seen for any other processes?

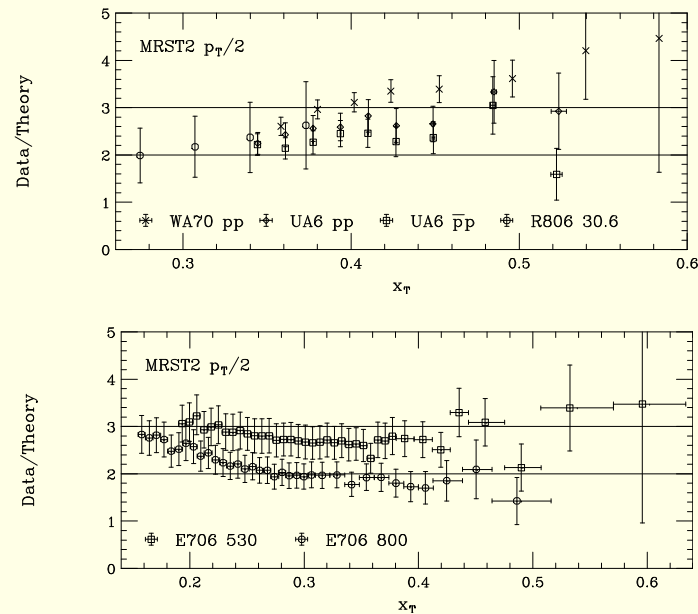

**Yes - Inclusive single hadron production!**

- Situation reviewed by Aurenche, Fontannaz, Guillet, Kniehl, and Werlen, hep-ph/9910252

## Example plot for direct photon production

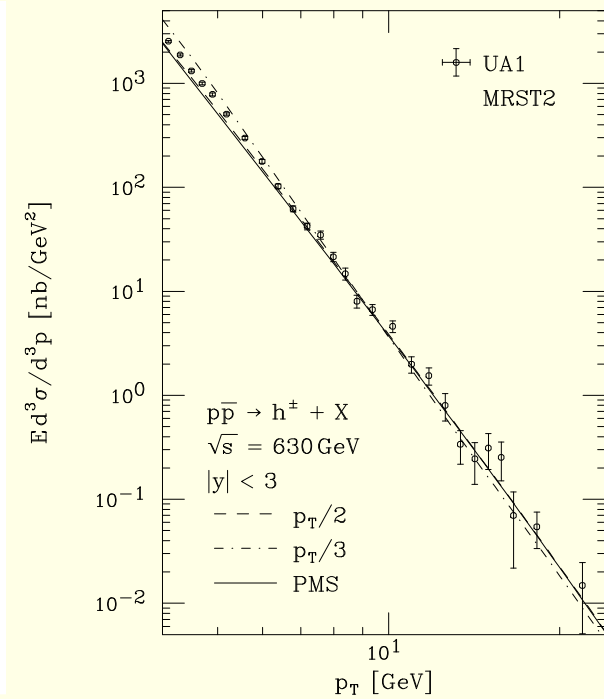

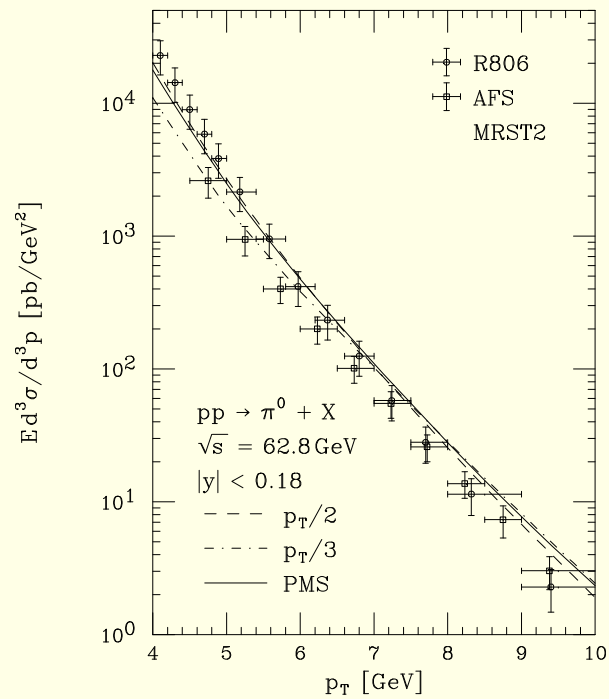

And two for  $\pi^0$  production

See similar excesses of data over theory

But a strange thing happens as one goes up in energy...

Agreement between theory and data gets better at higher energies *and at lower  $p_T$ 's!*

## So where do we stand?

1. Situation with fixed target direct photon production is confused by some disagreement between experiments
  - ▷ See Apanasevich et al., hep-ph/0007191 for a discussion of the systematics of  $\gamma/\pi^0$  ratios and consistency between experiments
2. All experiments see an excess of data over theory for single hadron inclusive production at fixed target energies
3. Agreement between theory and data for single hadron production improves with increasing energy and is excellent by  $\sqrt{s} = 200$  GeV
4. Likely that we need an *improved method of calculating single particle inclusive cross sections* in the fixed target energy range - one that would improve agreement for both photon and hadron production
5. A reassessment of systematic errors on the existing fixed target photon experiments might also help resolve the discrepancies between data sets

## Theoretical Ideas and Scenarios

Start by considering the case of single hadron production where all experiments in the fixed target regime see an excess of data over theory

- The steeply falling spectra in the fixed target region force the fragmentation variable  $z$  to be near one. As one goes up in energy the distributions flatten somewhat and  $\langle z \rangle$  decreases
- Fragmentation functions are not well constrained by data at high values of  $z$
- Fragmentation functions behave as  $(1 - z)^n$  with  $n \approx 2 - 3$ .
- As  $z \rightarrow 1$  large logarithms of  $(1 - z)$  should be resummed

Resummation may offer a way of significantly increasing the fixed target predictions ( $\langle z \rangle$  near 1) while not raising the already successful higher energy predictions too much (here  $\langle z \rangle \ll 1$ )

## Threshold Resummation

### Basic Physics -

- For inclusive calculations singularities from soft real gluon emission cancel against infrared singularities from virtual gluon emission
- Limitations on real gluon emission imposed by phase space constraints can upset this cancellation
- Singular terms still cancel, but there can be large logarithmic remainders
- Classic example is thrust distribution in  $e^+e^- \rightarrow jets$

See George Sterman's resummation lecture at this school

## High- $p_T$ particle production

- For typical fixed target energies the pdfs are evaluated at rather large  $x$  values and the fragmentation functions are evaluated at large  $z$
- For example,  $\sqrt{s} = 30$  GeV and  $p_T = 7.5$  GeV gives  $x_T = .5$
- Steeply falling pdfs and fragmentation functions constrain real gluon emission when high- $p_T$  is required since it costs a significant amount of the parton-parton center-of-mass energy to emit additional partons beyond the one that is fragmenting into the observed hadron.
- Phase space for gluon emission is limited near kinematic threshold in the parton-parton scattering subprocess for producing the hadron with the observed value of  $p_T$

Define  $v = 1 + t/s$  and  $w = -u/(s + t)$ .

Threshold occurs at  $w = 1$  ( $s + t + u = 0$ )

Soft gluons emission gives rise to terms in the partonic cross sections which behave like  $\alpha_s^m \left( \frac{\ln^n(1-w)}{1-w} \right)_+$

Can sum leading logs ( $n = 2m - 1$ ), next-to-leading-logs ( $n = 2m - 2$ ), etc.

## Application to the $\pi^0$ cross section

- Paper by de Florian and Vogelsang (hep-ph/0501258) applies threshold resummation to  $\pi^0$  production
- Large values of the fragmentation variable  $z$  relevant for fixed target energies leads to large threshold resummation corrections there.
- Enhancement is strongly energy dependent since the relevant values of  $z$  decrease as one goes to higher energies at fixed  $p_T$ .
- Enhancement is larger than that observed in jet production since the jet cross section doesn't involve fragmentation functions

- Blue curves include the resummation corrections properly matched to an existing NLO calculation in order to avoid double counting.
- Note the reduced scale dependence of the resummed results.

- Note reduced enhancement at RHIC energy compared to the previous fixed target results

## What about direct photons? Can threshold resummation help?

- Example application to the fixed target data - N. Kidonakis and J.F. Owens, Phys. Rev. D61, 094004, 2000; hep-ph/9912388
- Fixed target region dominated by annihilation and Compton subprocesses
- Fragmentation doesn't play as large a role as at higher energies since it costs extra energy to have a photon produced by fragmentation
- No significant enhancement to the annihilation and Compton terms
- Reduced scale dependence observed

But...

- The fragmentation contribution is *not* zero at fixed target energies
- Vogelsang and de Florian had previously shown that the fragmentation contribution in *hadro*production was significantly enhanced by threshold resummation
- They subsequently applied the formalism to direct photons in hep-ph/0506150
- Relative contribution of fragmentation versus direct *is* enhanced

- Resumming the fragmentation component results in a larger increase than if just the direct component is resummed
- Still isn't enough to describe the E-706 results

Resummation *can* result in a good description of the UA-6  $pp$  data

- Fragmentation component largely cancels in the  $\bar{p}p - pp$  difference, so the previous good agreement for this is retained
- Enhancement decreases rapidly with energy as in the hadroproduction case so that agreement with higher energy data is retained

## Bottom line on threshold resummation

- Provides reduced scale dependence
- Provides an enhancement in the fixed target regime, but the effect is much smaller at higher energies
- Can improve the agreement with some fixed target experiments without adversely affecting the agreement at higher energies
- *Joint resummation* (see Sterman and Vogelsang - hep-ph/0409234) includes parton recoil (or  $k_T$ ) effects which can be important at low  $p_T$
- See my 2005 CTEQ lecture for a discussion of joint resummation

So where do we stand?

- Situation recently reviewed by Aurenche, Fontannaz, Guillet, Pilon, and Werlen in hep-ph/0602133, Phys. Rev. D73:094007,2006.
- Incorporated new data from DØ and PHENIX (as discussed earlier)
- All calculations done with the JETPHOX package
- CTEQ6M pdfs used along with the Bourhis-Fontannaz-Guillet photon fragmentation functions
- All scales set equal to  $p_T/2$  except where noted

Excellent agreement between NLO QCD and the new DØ data (note that these data have  $p_T$  greater than 20 GeV)

Agreement with the PHENIX data (only statistical errors shown) is also excellent

Data/theory for collider and fixed target data shows a reasonably consistent comparison with some exceptions

Same as the previous figure, except on a linear  $x_T$  scale to emphasize the fixed target region at large  $x_T$

CDF data at 1.8 TeV (left) and CDF, and DØ, and UA-2 data at 630 GeV (right)

Is there a significant slope? Not with the errors shown...

Of course, there is always the visual aspect of how the data are plotted

The CDF and UA-2 data are the same in each plot, but the calculation on the right is from W. Vogelsang using CTEQ5M pdfs

Plot data at different energies versus  $x_T = 2p_T/\sqrt{s}$

## Comments

- Systematic errors cancel when comparing data from the same experiment (CDF) at different energies
- $x_T$  plot suggests that something is missing since the pdfs are being probed at about the same  $x$  values so the difference between theory and experiment should be similar for the two energies - and this is not the case

There is still room for theoretical improvement, *e.g.*, resummation, in describing the  $p_T$  distribution, especially at the low- $p_T$  end

This is a summary of the world's data on direct photon production. There is a reasonably consistent picture covering 9 orders of magnitude

## Summary and Conclusions

1. Examining  $\gamma$ -jet observables suggests that high- $p_T$  photons are produced in accordance with the expectations based on QCD
2. There is broad agreement between the theory and most experimental results for the photon  $p_T$  distribution
3. Photoproduction observables confirm that QCD matrix elements give a good description of photon interactions there, as well
4. Threshold resummation has been shown to play an important role in hadroproduction at fixed target energies and can offer some improvement for direct photons
  - Enhances the fragmentation contribution more than was previously anticipated in the fixed target regime
  - Effects are reduced at collider energies as the since smaller values of  $x_T$  are probed
  - Recoil or  $k_T$  effects can be included using joint resummation

## Parting Words

New data sets have helped confirm that overall there is a reasonably consistent picture of direct photon production provided by QCD which has now been tested over 9 orders of magnitude in the cross section, although there are still some regions where a detailed description will require additional study

## Appendix: some miscellaneous and hopefully useful stuff

### 1. Check out the CTEQ web page at [www.cteq.org](http://www.cteq.org)

- information on past summer schools, including transparencies of many of the lectures
- information and links for parton distributions
- CTEQ List of Challenges in Perturbative QCD
- CTEQ Pedagogical Page
- CTEQ Handbook of Perturbative QCD

### 2. Four-vectors and rapidity

- rapidity is defined as  $y = \frac{1}{2} \ln \frac{E+p_z}{E-p_z}$ . For massless particles this reduces to the pseudorapidity which is defined as  $\eta = \ln \cot \theta/2$ .
- the four-vector for a massless particle with transverse momentum  $p_T$  and rapidity  $y$  may be conveniently expressed as

$$p^\mu = (p_T \cosh y, p_T, 0, p_T \sinh y)$$

### 3. Mandelstam variables

- For a two-body process  $p_1 + p_2 \rightarrow p_3 + p_4$  the three Mandelstam variables are defined as

$$s = (p_1 + p_2)^2$$

$$t = (p_1 - p_3)^2$$

$$u = (p_1 - p_4)^2$$

- For processes with more particles one sometimes encounters variables such as  $s_{ij} = (p_i + p_j)^2$  which is just the squared invariant mass of particles  $i$  and  $j$  and  $t_{ij} = (p_i - p_j)^2$  which is the squared four-momentum transfer between particles  $i$  and  $j$ .

4. Another example: direct photon production  $qg \rightarrow \gamma + q$

- four-vectors in the hadron-hadron center-of-mass frame

$$p_q = \frac{\sqrt{s}}{2} x_a (1, 0, 0, 1)$$

$$p_g = \frac{\sqrt{s}}{2} x_b (1, 0, 0, -1)$$

$$p_\gamma = p_T (\cosh y, 1, 0, \sinh y)$$

- Substituting these four-vectors into the expressions for the Mandelstam variables above yields

$$\hat{s} = x_a x_b s$$

$$\hat{t} = -x_a p_T \sqrt{s} e^{-y}$$

$$\hat{u} = -x_b p_T \sqrt{s} e^y$$

- $\hat{s}$  is often used to denote a variable at the parton level.

## 5. Convolutions

- The symbol  $\otimes$  is sometimes used to denote a convolution:

$$\begin{aligned} f \otimes g &= \int_0^1 dy \int_0^1 dz f(y) g(z) \delta(x - yz) \\ &= \int_x^1 \frac{dz}{z} f(x/z) g(z) \end{aligned}$$

## 1. Subprocesses and angular distributions

- The two lowest order subprocesses for direct photon production are (in units of  $\pi\alpha\alpha_s/\hat{s}^2$ )

$$\begin{aligned}\frac{d\sigma}{d\hat{t}}(gq \rightarrow \gamma q) &= -\frac{e_q^2}{3} \left[ \frac{\hat{u}}{\hat{s}} + \frac{\hat{s}}{\hat{u}} \right] \\ \frac{d\sigma}{d\hat{t}}(q\bar{q} \rightarrow \gamma g) &= \frac{8}{9}e_q^2 \left[ \frac{\hat{u}}{\hat{t}} + \frac{\hat{t}}{\hat{u}} \right]\end{aligned}$$

- whereas the dominant parton-parton scattering subprocesses for hadroproduction are (in units of  $\pi\alpha_s^2/\hat{s}^2$ )

$$\begin{aligned}\frac{d\sigma}{d\hat{t}}(qq' \rightarrow qq') &= \frac{4}{9} \left[ \frac{\hat{s}^2 + \hat{u}^2}{\hat{t}^2} \right] \\ \frac{d\sigma}{d\hat{t}}(qg \rightarrow qg) &= -\frac{4}{9} \left[ \frac{\hat{s}}{\hat{u}} + \frac{\hat{u}}{\hat{s}} \right] + \frac{\hat{s}^2 + \hat{u}^2}{\hat{t}^2} \\ \frac{d\sigma}{d\hat{t}}(gg \rightarrow gg) &= \frac{9}{2} \left[ 3 - \frac{\hat{t}\hat{u}}{\hat{s}^2} - \frac{\hat{s}\hat{u}}{\hat{t}^2} - \frac{\hat{s}\hat{t}}{\hat{u}^2} \right]\end{aligned}$$

- In the parton-parton center-of-mass frame, one can write

$$\begin{aligned}\hat{t} &= -\frac{\hat{s}}{2} (1 - \cos(\theta^*)) \\ \hat{u} &= -\frac{\hat{s}}{2} (1 + \cos(\theta^*))\end{aligned}$$

- Therefore, as  $\cos(\theta^*) \rightarrow 1(-1)$ ,  $\hat{t}(\hat{u}) \rightarrow 0$ . Hence, in this limit, the first two subprocesses on the preceding page behave as  $(1 - |\cos(\theta^*)|)^{-1}$  while the next three behave as  $(1 - |\cos(\theta^*)|)^{-2}$ .

## 1. Center of mass scattering angle

Start in the parton-parton center of mass frame where one has

$$\begin{aligned} p_1 &= \frac{\sqrt{\hat{s}}}{2} (1, 0, 0, 1) & p_2 &= \frac{\sqrt{\hat{s}}}{2} (1, 0, 0, -1) \\ p_3 &= \frac{\sqrt{\hat{s}}}{2} (1, \sin \theta^*, 0, \cos \theta^*) & p_4 &= \frac{\sqrt{\hat{s}}}{2} (1, -\sin \theta^*, 0, -\cos \theta^*) \end{aligned}$$

from which one can derive

$$\hat{t} = -\frac{\hat{s}}{2} (1 - \cos(\theta^*)) \quad \hat{u} = -\frac{\hat{s}}{2} (1 + \cos(\theta^*)) .$$

Next, write the parton four-vectors in the hadron-hadron frame as

$$\begin{aligned} p_1 &= \frac{\sqrt{s}}{2} x_a (1, 0, 0, 1) \\ p_2 &= \frac{\sqrt{s}}{2} x_b (1, 0, 0, -1) \\ p_3 &= p_T (\cosh y_3, 1, 0, \sinh y_3) \\ p_4 &= p_T (\cosh y_4, -1, 0, \sinh y_4) \end{aligned}$$

which can be used to derive

$$\begin{aligned}\hat{t} &= -\sqrt{s}x_ap_Te^{-y_3} \\ \hat{u} &= -\sqrt{s}x_ap_Te^{-y_4}.\end{aligned}$$

From these two sets of expressions one can obtain

$$\frac{\hat{t}}{\hat{u}} = e^{-(y_3-y_4)} = \frac{1 - \cos \theta^*}{1 + \cos \theta^*}.$$

It then follows that

$$\cos \theta^* = \tanh \frac{y_3 - y_4}{2}.$$

8. Some comments on the asymptotic solution of the evolution equations for parton distributions in a photon

- Rewrite the evolution equations by taking moments of both sides using the following definitions:

$$M_q^n = \int_0^1 dx \, x^{n-1} \, G_{q/\gamma}(x)$$

$$M_g^n = \int_0^1 dx \, x^{n-1} \, G_{g/\gamma}(x)$$

$$A_{ij}^n = \frac{1}{2\pi b} \int_0^1 dx \, x^{n-1} \, P_{ij}(x)$$

$$a^n = \frac{\alpha}{2\pi} \int_0^1 dx \, x^{n-1} \, P_{q\gamma}$$

$$\alpha_s(t) = \frac{1}{bt}$$

where  $t = \ln(Q^2/\Lambda^2)$ .

- The evolution equations can now be written as

$$\begin{aligned}\frac{dM_q^n}{dt} &= e_q^2 a^n + \frac{1}{t} [A_{qq}^n M_q^n + A_{qg}^n M_g^n] \\ \frac{dM_g^n}{dt} &= \frac{1}{t} \left[ \sum_q A_{gq}^n M_q^n + A_{gg}^n M_g^n \right]\end{aligned}$$

- If each of the moments is proportional to  $t$ , the  $t$  dependence drops out of the equations and they may be solved algebraically

- The asymptotic solution is

$$\begin{aligned}
M_q^n &= a^n \left( \frac{e_q^2 - 5/18}{1 - A_{qq}^n} + \frac{5}{18} \frac{1 - A_{gg}^n}{F^n} \right) t \\
M_g^n &= \frac{5f}{9} a^n \frac{A_{gg}^n}{F^n} t \\
F^n &= 1 - A_{qq}^n - A_{gg}^n + A_{qq}^n A_{gg}^n - 2f A_{qg}^n A_{gq}^n
\end{aligned}$$

where  $f$  is the number of flavors

- Note how the moments are each proportional to  $t$
- Compare to the case where  $P_{q\gamma} = 0$  where the moments are of the form

$$M^n(t_0) \left( \frac{t}{t_0} \right)^{A^n}$$

- Note that one can add any solution of the homogeneous evolution equations to this asymptotic solution

## 1. Phase Space Slicing Monte Carlo

- See B. Harris and J.F. Owens hep-ph/0102128, Phys. Rev. **D65** 094032 (2002).
- Work in  $n=4-2\epsilon$  dimensions using dimensional regularization
- Notation:
  - At the parton level:  $p_1 + p_2 \rightarrow p_3 + p_4 + p_5$
  - Let  $s_{ij} = (p_i + p_j)^2$  and  $t_{ij} = (p_i - p_j)^2$
- Partition  $2 \rightarrow 3$  phase space into three regions
  1. Soft: gluon energy  $E_g < \delta_s \sqrt{s_{12}}/2$
  2. Collinear:  $s_{ij}$  or  $|t_{ij}| < \delta_c s_{12}$
  3. Finite: everything else

- In the soft region use the soft gluon approximation to generate a simple expression for the squared matrix element which can be integrated by hand
- In the collinear region use the leading pole approximation to generate a simple expression which can be integrated by hand.
- Resulting expressions have explicit poles from soft and collinear singularities
- Factorize initial and final state mass singularities and absorb into the fragmentation and distribution functions
- Add soft and collinear integrated results to the  $2 \rightarrow 2$  contributions – singularities cancel
- Generate finite region contributions in 4 dimensions using usual Monte Carlo techniques
- End result is a set of two-body weights and a set of three-body weights.
- Both are finite and both depend on the cutoffs  $\delta_s$  and  $\delta_c$

Cutoff dependence cancels for sufficiently small cutoffs when the two sets of weights are added at the histogramming stage

Simple example - consider the integral of a quantity which has a pole at  $x = 0$ .

Using dimensional regularization, one has an integral of the form

$$F = \int_0^1 dx x^{-1-\epsilon} f(x).$$

For  $x$  very near zero, approximate  $f(x)$  by  $f(0)$  yielding

$$F \approx f(0) \int_0^\delta dx x^{-1-\epsilon} + \int_\delta^1 dx x^{-1-\epsilon} f(x).$$

The first integral can be done analytically. The second is finite and can be evaluated with  $\epsilon = 0$ .

$$F \approx -\frac{f(0)}{\epsilon} + f(0) \log \delta + \int_\delta^1 dx \frac{f(x)}{x}.$$

The second integral can be done numerically. The dependence on the cutoff  $\delta$  cancels for sufficiently small values of  $\delta$
